Abstract It is known that storage capacity per synapse increases by synaptic pruning in the case of a correlation-type associative memory model. However, the storage capacity of the whole network then decreases. To overcome this difficulty, we propose that the connecting rate is decreased while keeping the total number of synapses constant by introducing delayed synapses. First, we re-derive the Yanai-Kim theory by employing the statistical neurodynamics. Next, we derive macroscopic steady state equations of the model by using the discrete Fourier transformation. Furthermore, two types of synaptic prunings are treated analytically. As a result, it becomes clear that in both prunings, the storage capacity increases as the length of delay increases and the connecting rate of the synapses decreases when the total number of synapses is constant. These results theoretically support the significance of pruning following over-growth of synapses in the brain, and strongly suggest that the brain prefers to store dynamic attractors such as sequences and limit cycles, rather than equilibrium states.

Key words associative memory, neural network, delay, synaptic pruning, statistical neurodynamics

1. Introduction

Robustness against noise and damage is often given as a positive feature of neural networks. Therefore, it is important to analyze neural networks with respect to synaptic pruning. Particularly in the case of correlation-type associative memory [1], models with randomly pruned synapses have been discussed in detail [2]–[5]. As a result, it became quantitatively clear that synapse efficiency, which is defined by storage capacity per synapse, increases by synaptic pruning, although storage capacity of the whole network decreases.

On the other hand, it is universally observed that synapses
are pruned following over-growth in real neural systems [5]–[15]. Though the functional significance of this phenomenon in not known, Chechik et al. recently proposed the following hypothesis[5]. They considered cutting synapses that are lightly weighted after learning with an excess of synapses, expecting synapse efficiency to increase by such systematic pruning. Therefore, they supposed that increasing synapse efficiency in that way gives functional significance to synaptic pruning following over-growth. They used a correlation-type auto-associative memory model to verify this hypothesis from a theoretical standpoint. After correlation learning, they left heavily weighted synapses in the model, in which all neurons are fully connected. Through computer simulations, they showed that the synapse efficiency increases by obtaining storage capacity. In this paper, synaptic pruning as described above is called systematic pruning. Though the hypothesis of Chechik et al. is interesting as neuroscience, there are some unclear or imperfect points from the theoretical viewpoint: for example, what degree of systematic pruning is more efficient than random pruning. Therefore, Mimura et al.[4] analyzed this system by using the SCSNA[21], which is the method of statistical mechanics. They showed that systematic pruning increases synapse efficiency by the order of $-\ln(1 - R)$ over random pruning at the limit when $R$ approaches unity, where $R (0 \leq R \leq 1)$ is the rate of synaptic pruning. The important point in this case is that the storage capacity of the whole network decreases, though synapse efficiency increases by random pruning or systematic pruning.

To overcome this difficulty, we propose to decrease the connecting rate while keeping the total number of synapses constant by introducing delayed synapses with respect to a discrete synchronous-type model. In this model, the storage capacity is expected to grow with increases in synapse efficiency because synapse efficiency increases by synaptic pruning, while the total number of synapses remains constant. The discrete synchronous-type model with delayed synapses [16], [24], [27] was proposed by Fukushima [16]. Yanai and Kim [24] theoretically analyzed this model with the statistical neurodynamics[22]. Their theory closely agrees with the results of our computer simulation.

In this paper, after defining the model, we re-derive the Yanai-Kim theory[24], [23] using the statistical neurodynamics [22], involving macrodynamical calculations for a network with delayed synapses. The Yanai-Kim theory needs a computational complexity of $O(L^{4}t)$ to obtain the macrodynamics, where $L$ and $t$ are the length of delay and the time step, respectively. Therefore, this theory is intractable for discussing macroscopic properties at the limit where $L$ is extremely large [26]. Thus, accounting for the parallel symmetry of time steps, which holds in the steady state of the Yanai-Kim theory, we derive the macroscopic steady state equations by employing the discrete Fourier transformation, where the computational complexity does not formally depend on $L$. Using the derived steady state equations, storage capacities can be quantitatively discussed even for a large $L$ limit.

Next, synaptic pruning in the delayed network is treated theoretically, and storage capacities are evaluated quantitatively. We deal with two types of pruning: random pruning and systematic pruning. As a result, it becomes clear that in both types of pruning, storage capacity increases as the length of delay increases, while the connecting rate of synapses decreases where the total number of synapses is constant. Moreover, an interesting fact becomes clear; that is, the storage capacity asymptotically approaches $2/\pi$ by random pruning. In contrast, the storage capacity diverges in proportion to the logarithm of the length of delay $L$ by systematic pruning.

2. Delayed Network

2.1 Model

The structure of a delayed network discussed in this paper is shown in Figure 1. This figure corresponds to the case of fully synaptic connections, meaning no synaptic pruning. The network has $N$ neurons, and $L - 1$ serial delay elements are connected to each neuron. All neurons, as well as all delay elements, have synaptic connections with all neurons. In this neural network, all neurons and all delay elements change their states simultaneously, i.e., this network employs a discrete synchronous updating rule. The output of each neuron is determined by

$$x_i^{t+1} = F(u_i^t)$$

$$F(\cdot) = \text{sgn}(\cdot)$$

$$u_i^t = \sum_{j=0}^{L-1} \sum_{j=1}^{N} J_{ij} x_j^{t-j},$$

where $x_i^t$ denotes the output of the $i$th neuron at time $t$, and $J_{ij}$ denotes the connection weight from the $i$th delay elements of the $j$th neuron to the $i$th neuron. Here, $\text{sgn}(u)$ is the sign function defined as

$$\text{sgn}(u) = \begin{cases} +1, & u \geq 0 \\ -1, & u < 0 \end{cases}$$

In this paper, the limit $N \to \infty$ is used unless stated otherwise.

Let us consider the storing sequence of $\alpha N$ memory patterns, $\xi^1 \to \xi^2 \to \cdots \to \xi^\mu \to \cdots \to \xi^{\alpha N}$. Here, $\alpha$ and $\alpha N$ are the loading rate and the length of the sequence, respectively. Each component of $\xi^\mu$ is assumed to be an independent
random variable that takes a value of either $+1$ or $-1$ according to the following probabilities,

$$\text{Prob}[\xi_i^t = \pm 1] = \frac{1}{2}$$  \hspace{0.5cm} (5)

The synaptic weight $J_{ij}$ is determined by correlation learning:

$$J_{ij} = \frac{\alpha}{N} \sum_{\mu} \xi_i^{\mu+t} \xi_j^t$$  \hspace{0.5cm} (6)

where $\alpha$ is the strength of the $\mu$th delay step.

Correlation learning is an algorithm based on Hebb rule, and it is inferior to the error correcting learning in terms of storage capacity. However, as seen in eqn (6), it is not necessary to re-learn all patterns that were stored in the past when adding new patterns. Furthermore, correlation learning has been analyzed by many researchers due to its simplicity.

2.2 Dynamical Behaviors of Macroscopic Order

Parameters by Statistical Neurodynamics

In the case of a small loading rate $\alpha$, if a state close to one or some of the patterns stored as a sequence are given to the network, the stored sequence of memory patterns is retrieved. However, when the loading rate $\alpha$ increases, the memory fails at a certain $\alpha$. That is, even if a state close to one or some of the patterns stored as a sequence is given to the network, the state of the network tends to omit the stored sequence of memory patterns. Moreover, even if one or some of the patterns themselves are given to the network, the state of the network tends to leave the stored sequence of memory patterns. This phenomenon of the memory suddenly becoming unstable at a critical loading rate can be considered a kind of phase transition. Here, the storage capacity $\alpha_C$ is defined as the critical loading rate where recalling becomes unstable.

We define the overlap, or direction cosine, between a state $x^t = (x_i^t)$ appearing in a recall process at time $t$ and an embedded pattern $\xi^t = (\xi_i^t)$ as

$$m^t = \frac{1}{N} \sum_{i=1}^{N} \xi_i^t x_i^t.$$  \hspace{0.5cm} (7)

Using this definition, when the state of the network at time $t$ and the $\mu$th pattern agree perfectly, the overlap $m^t$ is equal to unity. When they have no correlation, the overlap $m^t$ is equal to zero. Therefore, the overlap provides a means of measuring recall quality.

Amari and Maginu [22] proposed the statistical neurodynamics. This analytical method handles the dynamical behavior of recurrent neural network macroscopically, where crosstalk noise is regarded as a Gaussian random variable with a mean of zero and a time-dependent variance of $\sigma_i^2$. They then derived recursive relations for the variance and the overlap.

Using eqns (1)-(7), we can derive the following macrodynamical equations.

$$\sigma_i^2 = \sum_{\ell=0}^{L-1} \sum_{\tau=0}^{L-1} \alpha \sigma_i^{\ell} \sigma_i^{\ell+\tau}.$$  \hspace{0.5cm} (8)

$$v_{i,l+l-\tau} = \alpha \delta_{\mu,\mu'}$$

$$+ U_{i-l-l} \sum_{\ell=0}^{L-1} \sum_{\tau=0}^{L-1} c_{i,\ell,\tau} v_i^{\ell-\ell-\tau-l-\mu}$$

$$+ \alpha (c_{i,\ell,\tau-1} U_{i-l-\tau} + c_{i,\ell-1,\tau} U_{i-l-\tau-1}),$$  \hspace{0.5cm} (9)

$$U_i = \sqrt{\frac{2}{\pi}} \frac{1}{\sigma_{i+1}} \exp \left( - \frac{\left( x_i^{l+1} \right)^2}{2 \sigma_i^{l+1}} \right),$$  \hspace{0.5cm} (10)

$$s_i^l = \sum_{\ell=0}^{L-1} c_i m_i^{\ell-1},$$  \hspace{0.5cm} (11)

$$m_i^{l+1} = \text{erf} \left( \frac{s_i^l}{\sqrt{2} \sigma_i^{l+1}} \right),$$  \hspace{0.5cm} (12)

where $m_i$ denotes $m_i^t$. If $t < 0$, $m_i = 0$ and $U_i = 0$. If $k < 0$, $c_i = 0$. If either $k < 0$ or $k' < 0$, $v_{i,\mu,\mu'} = 0$. The expression $\text{erf}(x) \equiv \frac{2}{\sqrt{\pi}} \int_0^x \exp(-u^2) \, du$ denotes the error function. In this paper, the initial condition is that the states of all
neurons and all delay elements are set to be the stored in pattern sequences. In this case, \( m_l = 1 \) \((l = 0, \ldots, L - 1)\) and \( v_{l,t} = \alpha \) \((l = 0, \ldots, L - 1)\).

We note that the derived macrodynamical equations and the Yanai-Kim theory\[24], [25] coincide.

2.3 Macroscopic Steady State Analysis by Discrete Fourier Transformation and Discussion

The Yanai-Kim theory re-derived in the previous section, which involves the macrodynamical equations obtained by the statistical neurodynamics, needs a computational complexity of \( O(L^4 t) \) to obtain the macrodynamics as shown in eqns (8) and (9), where \( L \) and \( t \) are the length of delay and the time step, respectively. Therefore, in this method, it is intractable to investigate the critical loading rate for a large \( L \) limit, i.e., the asymptotic behavior of the storage capacity in a large \( L \) limit. Thus, in this section, we consider the Yanai-Kim theory in a steady state and derive the macroscopic steady state equations of the delayed network. Furthermore, the storage capacity is analyzed for a large \( L \) by solving the derived equations numerically\[25].

For simplicity, let us assume that \( \alpha = 1 \), \( \omega = 0, \ldots, L - 1 \). In a steady state, \( v_{l,t-\omega} \) can be expressed as \( v_{l,t-\omega} \) because of the parallel symmetry in terms of time step. Using the discrete Fourier transformation and the inverse discrete Fourier transformation, we obtain

\[
\sigma^2 = \sum_{n=-L}^{L-1} (L - |n|) \lim_{t \to \infty} \frac{1}{2T} \sum_{n=L-t}^{T} V(r) e^{j2\pi \frac{nr}{2T}}, \quad (13)
\]

From eqns (10)-(12) and (13), we can obtain the steady state equations in terms of the network’s macroscopic variables as eqns (14)-(17).

\[
\sigma^2 = \int_{-\frac{\pi}{2}}^{\frac{\pi}{2}} \frac{1}{2} \alpha \left[ \int_{-\frac{\pi}{2}}^{\frac{\pi}{2}} \left( 1 - U \right) \sin(\pi x) + U \sin \left( (2L + 1) \pi x \right) \left( 1 - \cos(2L \pi x) \right) \right] dx
\]

\[
U = \sqrt{2 \frac{1}{\sigma} \exp \left( -\frac{s^2}{2\sigma^2} \right)}, \quad (14)
\]

\[
s = mL, \quad (15)
\]

\[
m = \text{erf} \left( \frac{s}{\sqrt{2\sigma}} \right), \quad (16)
\]

\[
\sigma^2 = \int_{-\frac{\pi}{2}}^{\frac{\pi}{2}} \frac{1}{2} \alpha \left( 1 - U \right) \sin(\pi x) + U \sin \left( (2L + 1) \pi x \right) \left( 1 - \cos(2L \pi x) \right) \left( 1 - \cos(2L \pi x) \right) \right] dx
\]

\[
\text{Figure 4 Relationship between loading rate } \alpha \text{ and overlap } m. \text{ These lines are obtained by solving steady state equations numerically. Storage capacity is } 0.195L, \text{ with a large } L \text{ limit.}
\]

Though the derived macroscopic steady state equations include a simple integral, their computational complexity does not formally depend on \( L \). Therefore, we can easily perform numerical calculations for a large \( L \). Figure 2 shows the results of theoretical calculation in cases where \( L = 1, 3 \) and \( 10 \), which are obtained by solving these equations numerically. Figure 3 shows the results of computer simulations. In these Figures, the abscissa is the loading rate \( \alpha \). In the computer simulations, the number of neurons is \( N = 500 \), and the steady state overlaps \( m_{\infty} \) are obtained by calculations with a sufficient number of steps. Eleven simulations were carried out for each combination of loading rate \( \alpha \) and length of delay \( L \). Data points \( * \), \( o \), \( \circ \), \( \bullet \) indicate the medians of the sixth largest values in the eleven trials. Error bars indicate the third and
the ninth largest values in the eleven trials. In each trial, the
loading rate is increased by adding new patterns.

These figures show that the steady states obtained by the
derived theory agree closely with those obtained by computer
simulation. Therefore, in the case of a large \( L \), only the theo-
retical calculations are executed. Figure 4 shows the results.
From this figure, we can see that the storage capacity increases
in proportion to the length of delay \( L \) with a large \( L \) limit and
a proportion constant of 0.195. In other words, the storage
capacity of the delayed network \( \alpha L \) equals 0.195 when the
length of delay \( L \) is large. Although the result indicating that
the delayed network’s storage capacity is in proportion to the
length of delay \( L \) may be trivial, the fact that this result has
been proven analytically is significant. Moreover, the propor-
tion constant 0.195 is a mathematically significant number be-
cause it represents the limit of the delayed network’s storage
capacity.

3. Synaptic Pruning

3.1 Necessity of Analyzing Synaptic Pruning

During brain development, the phenomenon of synaptic
pruning following over-growth \([3]–[15]\) is observed. Since this
pruning following over-growth seems to be a universal phe-
omenon occurring in almost all areas – visual cortex, motor
area, association area, and so on, it is important to analyze
synaptic pruning and to discuss its properties quantitatively.

In the case of a delayed network with no pruning, it is ob-
vious that storage capacity increases as the length of delay \( L \)
increases. On the contrary, it is interesting to analyze the stor-
ge capacity of a delayed network that has a constant number of
synapses by introducing synaptic pruning.

It has been reported that the synapse efficiency, which is de-
fining as storage capacity per synapse, increases due to synap-
tic pruning in networks with no delay elements\([2], [3]\). A cou-
ples of pruning can be considered, namely random pruning
and systematic pruning, which are typical methods\([2], [3], [5]\).
Mimura et al.\([4]\) showed that synapse efficiency converges to
\( \frac{2}{n} \) by random pruning, and diverges as \( \frac{2}{n} (-2 \ln c) \) at the limit
where the connecting rate \( c \) is extremely small. Here, the re-
lation between connecting rate \( c \) and pruning rate \( R \) is given
by \( c = 1 - R \). The important point here is that the storage
capacity of the whole network decreases, since the number of
synapses decreases.

In the following discussion, a delayed network with synaptic
pruning is analyzed on the basis of macrodynamical equations
and macroscopic steady state equations derived in the former
section. We consider two types of pruning —random pruning
and systematic pruning— for synaptic pruning.

3.2 Random Pruning

In this section, synapses of a delayed network are randomly
pruned. Random pruning of synapses can be realized with-
out any complicated control mechanisms, therefore, it is im-
portant to investigate its effect on the dynamical behavior of
pattern recalling and storage capacity.

In the random synaptic pruning model, synaptic connections
are constituted as
\[
J_{ij}^L = \frac{c_l c_j}{N_c} \sum \xi_i \xi_j^{l+i+1} \xi_j^c, \tag{18}
\]

\[
\text{Prob}(c_j = 1) = 1 - \text{Prob}(c_j = 0) = c, \tag{19}
\]

where \( c \) is the connecting rate.

Modifying eqn (18), we obtain
\[
J_{ij}^L = \frac{c_l c_j}{N_c} \sum \xi_i \xi_j^{l+i+1} \xi_j^c + \frac{c_l (c_j - c)}{N_c} \sum \xi_i \xi_j^{l+i+1} \xi_j^c \tag{20}
\]

We can obtain the macrodynamical equations for random
pruning as follows,
\[
\bar{\sigma}_t^2 = \sigma_t^2 + \frac{\alpha (1-c)}{c} \sum_{l=0}^{L-1} c_l^2, \tag{21}
\]

\[
\sigma_t^2 = \sum_{l=0}^{L-1} \sum_{\ell=0}^{L-1} q_{\ell l} v_{l+\ell-1-t}, \tag{22}
\]

\[
v_{l+\ell-1-t} = \alpha \delta_{l\ell} + U_{l+\ell-1-t} \sum_{l=0}^{L-1} \sum_{\ell=0}^{L-1} c_l c_{\ell} v_{l+\ell-1-t}, \tag{23}
\]

\[
U_t = \sqrt{\frac{2}{\pi \bar{\sigma}_{t-1}}} \exp \left( - \frac{\bar{s}^2}{2 \bar{\sigma}_{t-1}} \right), \tag{24}
\]

\[
\bar{s}^2 = \sum_{l=0}^{L-1} c_l m_{l-1}, \tag{25}
\]

\[
m_{l+1} = \text{erf} \left( \frac{s^2}{\sqrt{2 \bar{\sigma}_l}} \right), \tag{26}
\]

where the initial conditions are the same as in the case of a
fully connected network. \( \delta \) is Kronecker’s delta. Equation
(21) means that the variance \( \bar{\sigma}_t^2 \) after pruning is the sum of
the variance of cross-talk noise among patterns and the vari-
ance of new noise generated by pruning. Finally, as for a fully
connected network, the macroscopic steady state equations in
the case of random pruning become
\[
\bar{\sigma}_t^2 = \sigma_t^2 + \frac{\alpha (1-c)}{c} \sum_{l=0}^{L-1} c_l^2 \tag{27}
\]

\[
U_t = \sqrt{\frac{2}{\pi \bar{\sigma}}} \exp \left( - \frac{s^2}{2 \bar{\sigma}} \right) \tag{28}
\]

\[
s = mL \tag{29}
\]

\[
m = \text{erf} \left( \frac{s}{\sqrt{2 \bar{\sigma}}} \right) \tag{30}
\]
where $\sigma^2$ is given by eqn (14).

It is obvious that storage capacity increases with the length of delay $L$ if the connecting rate $c$ is constant. Therefore, the storage capacity $\alpha_C$ is investigated under the condition that $c \times L$ is constant. That means eqns (27)-(30) are solved numerically and the steady state overlaps $m_\infty$ are investigated using $c = 1/L$, where $c_2 = 1$. Figure 5 shows the results of theoretical calculations and computer simulations when $L = 1, 2, 3, 5$ and 10. In this figure, the abscissa is loading rate $\alpha$. In the computer simulations, the number of neurons is $N = 500$, and the steady state overlaps $m_\infty$ are obtained by calculations with a sufficient number of steps. Eleven simulations were carried out for each combination of loading rates $\alpha$ and length of delays $L$. Data points •, ○, ■, □, * indicate the medians of the sixth largest values in the eleven trials. Error bars indicate the third and the ninth largest values in the eleven trials. In each subsequent trial, the loading rate is increased by adding new patterns.

Figure 5 Relationship between loading rate $\alpha$ and overlap $m$ when synapses are randomly pruned. (theory(1) and computer simulation(8))

Figure 6 Relationship between loading rate $\alpha$ and overlap $m$ when synapses are randomly pruned. (theory)

Figure 5 displays the following. In the case of $L = 1\, (c = \frac{1}{c_2} = 1.0)$, that is fully connected with no delay elements, the recurrent neural network’s storage capacity $\alpha_C$ for sequential association is 0.269. This agrees with published values [28]-[30]. As the length of delay $L$ increases, storage capacity $\alpha_C$ increases though the total number of synapses is constant. This phenomenon is due to the time lag of synaptic inputs by delays that reduces statistical correlation among synaptic inputs. As a result, variance of the noise component decreases. This figure shows that theoretical results closely agree with the simulation results. Therefore, only a theoretical calculation is executed when the length of delay $L$ is large. Figure 6 shows the results.

In Figure 6, the property $L = \infty$ is obtained by setting $U = 0$. The storage capacity in this case is $2/\pi = 0.6366 \ldots$. Figure 6 shows that the storage capacity approaches this value asymptotically as $L$ increases.

### 3.3 Systematic Pruning

Chechik et al. [5] discussed the functional significance of synaptic pruning following over-growth on the basis of a correlation-type associative memory model. They pointed out that synapse efficiency, which is storage capacity per synapse, increases by cutting synapses that are lightly weighted after correlation learning.

Systematic pruning like that can be expressed by nonlinear function $f(\cdot)$ shown in Figure 7. Synapses in the range of $-z_{th} < z < +z_{th}$ are pruned by $f (\cdot)$. In this case, the relationship between the connection rate $c$ and $z_{th}$ is given by

$$c = \int_{\text{[-1/(c)]+\infty}} Dz = 1 - \text{erf}\left(\frac{z_{th}}{\sqrt{\alpha}}\right),$$

where $Dz$ stands for $\frac{1}{\sqrt{2\pi}}\exp\left(-\frac{z^2}{2}\right)dz$, and the integral is from $-\infty$ to $+\infty$.

In the systematic pruning model, synaptic connections are constituted by

$$J_{ij}^l = \frac{c_2 \sqrt{\alpha N}}{N} f\left(\frac{T_{ij}^l}{\theta_0}\right),$$

$$T_{ij}^l = \left(\frac{1}{\sqrt{\alpha N}}\right) \sum_{\mu} \epsilon_{ij}^{\theta_0 + 1 + \theta_{ij}^l} \xi_j.$$
Equation (33) is a stochastic variable that obeys normal distribution \( N [0,1] \).

Modifying the connection weight \( \Delta_{ij} \), [3], we obtain

\[
\Delta_{ij} = \frac{\alpha \sqrt{\alpha N}}{N} f \left( T_{ij}^{\hat{}} \right) = \frac{\alpha \sqrt{\alpha N}}{N} \left( JT_{ij}^{\hat{}} + \left( f \left( T_{ij}^{\hat{}} \right) - JT_{ij}^{\hat{}} \right) \right),
\]

where

\[
J = \int D x f(x),
\]

\[
= \int D x f(x).
\]

We can obtain the macrodynamical equations for systematic pruning as follows,

\[
\sigma_i^2 = \sigma_i^2 + \alpha \left( \bar{J}^2 - J^2 \right) \sum_{l=0}^{L-1} c_i^2,
\]

\[
\sigma^2 = J^2 + \sum_{l=0}^{L-1} \sum_{l'=0}^{L-1} c_i c_{l'} v_{l-l'}
\]

\[
\bar{J}^2 = \int D x (f(x))^2,
\]

\[
J = \int D x f(x),
\]

\[
v_{l-l'} = \alpha \delta_{l,l'}
\]

\[
+ U_{l-l'} \sum_{l=0}^{L-1} \sum_{l'=0}^{L-1} c_i c_{l'} v_{l-l'} + \alpha \left( c_{l-l'} U_{l-l'} + c_{l'-l} U_{l-l} \right),
\]

\[
U_l = \sqrt{\frac{2}{\pi}} \frac{1}{\sigma_{l-1}} \exp \left( -\frac{(x-\alpha)^2}{2\sigma_{l-1}^2} \right),
\]

\[
\delta = J \sum_{l=0}^{L-1} c_i m_{l-i},
\]

\[
m_{l+1} = \text{erf} \left( \frac{\delta}{\sqrt{2\sigma_{l+1}}} \right),
\]

where the initial conditions are the same as in the case of a fully connected network \( \delta \) is Kronecker’s delta. Eqn (38) means that the variance \( \sigma_i^2 \) after pruning is the sum of the variance \( \sigma_i^2 \) of cross-talk noise among patterns and the variance \( \alpha \left( \bar{J}^2 - J^2 \right) \sum_{l=0}^{L-1} c_i^2 \) of new noise generated by pruning. Finally, as in the case of full connections, the macroscopic steady state equations in the case of systematic pruning become

\[
\sigma^2 = \sigma^2 + \alpha \left( \frac{\sigma^2}{J^2} - 1 \right) \sum_{l=0}^{L-1} c_i^2,
\]

\[
U = \sqrt{\frac{2}{\pi}} \frac{1}{\sigma} \exp \left( -\frac{\delta^2}{2\sigma^2} \right),
\]

\[
s = mL,
\]

\[
m = \text{erf} \left( \frac{\delta}{\sqrt{2\sigma}} \right),
\]

where \( \sigma^2 \) is given by eqn (14).

As for random pruning, the storage capacity \( \alpha_c \) is investigated under the condition that \( c \times L \) is constant. That means eqns (46)-(49) are solved numerically, and the steady state overlaps \( m_{\alpha} \) are investigated using \( c = 1/L \), where \( \alpha = 1 \).

Figure 8 shows the results of theoretical calculations and computer simulations when \( L = 1, 2, 3, 5 \) and \( 10 \). In this figure, the abscissa is the loading rate \( \alpha \). In the computer simulations, the number of neurons is \( N = 500 \), and the steady state overlaps \( m_{\alpha} \) are obtained by calculations with a sufficient number of steps. Eleven simulations were carried out for each combination of loading rate \( \alpha \) and length of delays \( L \). Data points \( \bullet, *, \square, \circ \) indicate the medians of the sixth largest values in the eleven trials. Error bars indicate the third and the ninth largest values in the eleven trials. In each trial, the loading rate is increased by adding new patterns.

Figure 8 Relationship between loading rate \( \alpha \) and overlap \( m \) when synapses are systematically pruned. (Theory(1) and computer simulation(8))

Figure 9 Relationship between loading rate \( \alpha \) and overlap \( m \) when synapses are systematically pruned. (Theory)

Figure 8 shows the following. As the length of delay \( L \) increases, storage capacity \( \alpha_c \) increases though the total number of synapses is constant. This figure shows that theoretical
results closely agree with the simulation results. Therefore, only a theoretical calculation is executed when the length of delay $L$ is large. Figure 9 shows the results.

Figure 9 shows the following. As the length of delay $L$ increases, storage capacity $\alpha_C$ increases, though the total number of synapses is constant; the tendency to increase is different from that of random pruning. Storage capacity is in proportion to the logarithm of the length of delay $L$, and the proportion constant is 2.8, i.e., $\alpha_C = 2.8 \log L$. In the other words, for systematic pruning, storage capacity diverges with the increase in the length of delay $L$. It is amazing that the storage capacity diverges regardless of whether the total number of synapses is constant. However, this fact is also supported by Mimura et al. [4] described in Sec.3.1.

4. Conclusion

We analyzed a discrete synchronous-type model that adopts correlation learning by using the statistical neurodynamics, and discussed sequential associative memory by recurrent neural networks with synaptic delay and pruning. First, we re-derived the Yanai-Kim theory, which involves macrodynamical equations for the dynamics of the network with serial delay elements. Next, accounting for the parallel symmetry of the re-derived equations, we derived the macroscopic steady state equations of the model by using the discrete Fourier transformation. The storage capacity was analyzed quantitatively. As a result, we showed that the storage capacity is in proportion to the length of delay $L$ when the $L$ limit is large and the proportion constant is 0.195. Furthermore, two types of synaptic pruning were analyzed: random pruning and systematic pruning. As a result, it became clear that under both pruning conditions, the storage capacity grows with an increase in delay and decrease in the connecting rate when the total number of synapses is constant. Moreover, an interesting fact became clear: the storage capacity approaches $2/\pi$ asymptotically by random pruning. In contrast, the storage capacity diverges in proportion to the logarithm of the length of delay by systematic pruning. These results theoretically support the significance of pruning following over-growth of synapses in the brain [5]-[13] and strongly suggest that the brain prefers to store dynamic attractors such as sequences or limit cycles, rather than equilibrium states.

In this paper, we treated random patterns, in which each element takes $\pm 1$ with a probability of 0.5. It is interesting future work to treat sparse patterns in which each element takes $+1, 0$.
